A GENERAL COMPUTER DATA PROCESSING SYSTEM: DOCUMENTATION OF THE ATS-5 GROUND STATION MAGNETOMETER PROGRAM

INTRODUCTION

A computer program capable of transforming and displaying specific time-dependent data recorded on an indefinitely large number of tape reels is a common need within scientific activities. The ATS-5 Ground Station Magnetometer Data Processing Program described in this documentation is of this type. It is suggested that the data operations accomplished by this processing system are of sufficiently general application that the system could be used to process other types of data with little modification. To enable a determination of the applicability of this system for a particular data processing use, a list of these data operations is presented below. Also, a concept-level "plain language" flow chart for their implementation is presented in Appendix A, and a commented listing of the production program is presented in Appendix C. The program logic is summarized under "Main Program" on page 15, and in the flow chart in Appendix A. This documentation uses an original instructional device involving numbered comments to aid the reader to understand the program. This is explained more fully on pages 4 and 14.

The effectiveness with which the program has processed the ATS-5 data suggests that it successfully avoids the weak points of too much or too little sophistication which has troubled other data processing programs observed by the author. Data systems written by the author using the techniques described in this publication have kept the number of unprocessed ATS-5 flight and ground data tapes on hand to zero and are concise enough to be completed in four months by one experienced person. The production program card deck will be supplied upon request.

1. General Data Operations in this Program

- A. Expression of data time in terms of a single physical unit (milliseconds) for computational convenience for data extending over minutes, hours, days, or years (see explanation under "Data Time Value Assignment" on page 11).
- B. Selection of time intervals of data to be processed by designation of their beginning times (TI) and end times (TF) on program input cards in chronological order.
- C. Search through the tape to data with times within the time interval currently selected for processing.

D. Confirmation that the tape used in the computer run is the one in the data tape library bearing the data time intervals selected for processing by the TI, TF program input cards. This is done by print-out of the beginning and end time of the data tape mounted on the tape drive which shows if this tape contained the data time interval currently selected for processing as indicated by print-out of its TI and TF. This program proceeds to the next TI, TF selector card if the mounted data tape post-dates the first TI, TF selector card. It terminates the computer run if the end of the data tape is encountered while searching for or processing data in the currently selected time interval.

NOTE: In other programs using this general data processing scheme such as those for ATS-5 and OGO-6 satellite flight data which, contrary to this program, are intended to process many data tapes in a single computer run differing action is taken when the mounted tape does not contain data in the currently selected time interval. Instead, the computer operator is provided with on-line printer messages showing the begin and end time of each tape he mounts enabling him to ultimately mount the tape containing data in the currently selected time interval (also printed on-line) if this tape has been made available to him, and through some oversight he at first mounts some other tape. These programs permit the operator to proceed to the next TI, TF selector card if the proper tape is not available. Also, programs using this general data processing scheme avoid the considerable programming complication of a "data time span versus relevant data tape identification number" directory logic module for automatic on-line printer tape mounting requests. In these programs this directory function is achieved by designation of the data tape identification numbers in the sequence in which they are to be used in the run by the person submitting the program. This person refers to the data tape shipping slips for tape begin and end time information to do this. This scheme has been found practicable even when as many as 12 or more ATS-5 satellite PB data tapes have been submitted in a computer run directly producing output data displays. The sheet of on-line printer messages showing begin and end times of the time intervals selected for processing, the begin and end times of the data tapes actually mounted, and printed indications of the computer operator's response to the respective tape mount requests constitutes a report that would show any deviations from the data tape utilization instructions submitted with the job. The only prerequisite on the data organization on a tape for this general data processing scheme to process all data on it is that the data within any given file be in chronological order — the various files of the tape do not have to be. Also, it is permissible for data missing from a tape to appear on another tape.

- E. Ignore any data on the tape with time which is out of chronological order.
- F. Do processing unaffected by any missing data, i.e. irregular jumps in data times.
- G. Unpack the data values from their fields of various bit lengths in each logical record (a grouping of bits on tape comprising the data in a definite format which by repetition forms the data tape) into fortran variables for processing in the main program.
- H. Mathematical conversion of the data into appropriate physical units.
- I. Isolation of collections of data (referred to as Plot B arrays) of specific time intervals relative to the beginning of the day of data to do statistics on and/or to graphically display on microfilm as a function of time (termed the Plot B display).
- J. Obtain collections of time-averaged data points (referred to as Plot C arrays) to produce "quick-look" summarizing graphical microfilm plots of events over specific time intervals relative to the beginning of the day of data (termed the Plot C display). These "summary" microfilm frames appear right after the end of the microfilm frames which they summarize. The time interval over which an average is computed is a variable of the program presently set at 30 seconds.
- K. In graphical microfilm display, choice of ordinate and abscissa scale (independently) to display data plotted in any given frame with the best resolution. The choice of scale is based on the prevailing data sampling time interval for the abscissa scale, and the range in data values plotted in the microfilm frame for the ordinate scale.
- L. Display numerical values of processed data as a function of time on paper print-out.

2. Functions of this Documentation

A. Define the type of data processing accomplished by this program pointing out the methods used, and their usefulness for writing programs to do similar processing on data of other types (see Appendix A for flow chart illustrating how various general data operations are done in this program.)

- B. Describe the data, source of data, and data tape format specifically processed by this program (see Appendix B for the data tape and logical record format).
- C. Itemize all subroutines and their functions.
- D. Explain in detail the program logic using numerous plain language comments prefacing the program statements to which they apply (see program listings in Appendix C and detailed "Autoflow" flow chart in Appendix D). These comments are numbered to identify corresponding specific program statements in the program listing by comment number reference in explanations of program logic in the written documentation and in the flow charts in Appendices A and D.
- E. Describe the various display outputs of the program and show samples of them (see Appendices E, F, and G).

COMPUTER INFORMATION

The program is written for the IBM/360, Operating System release number 16 or higher with the new SCORS Stromberg Carlson 4020 plotter subroutine package. However, the main program can be used without change for any plotter since all plotting logic is "modular", i.e., done by subroutines called by the main program. To use the program to drive a plotter other than the SC4020, it is necessary only to replace the SC4020 subroutine calls by calls to the subroutine package of the replacing plotter.

The main program and all but one of the subroutines are in Fortran IV. A small subroutine named PICK used for unpacking the data values from the bit sequences in the logical records on the data tape is in IBM/360 Assembly Language. Subroutine PICK is sufficiently general to be used for data "unpacking" in a logical record of any format.

All program input and output operations are done by Fortran IV in the main program since IBM/360 Fortran has sufficiently versatile capabilities to read data tapes of arbitrary format without the need for the less simple I/O instructions of the assembly language.

The amount of IBM/360 core required by the program is 200,000 bytes. The IBM/360 computer time required on the Model 75 is about 20 minutes for each day of data. On the IBM/360 Model 91 the program runs twice as fast.

DATA DESCRIPTION AND SOURCE

The data read from a tape and processed by this program is raw magnetometer readings of the components of the geomagnetic field in the H, D, Z coordinate system (see Appendix H for definition) and readings from an additional experiment channel (called R readings) at a specific location on the earth's surface as a function of time. This location is at a Canadian geophysical ground station situated near the foot of the geomagnetic line of force passing through the ATS-5 satellite. Two such stations are operating: LYNN LAKE and THOMPSON in Manitoba, Canada. All of the data on a given tape will be from one of these stations. The output displays of the program are identified by labelling showing the name of the station to which they apply.

At both stations, data is written on the tapes by inexpensive tape decks fed by the magnetometer. The tape decks are specially designed to directly write the data on tape in physical records (a division of data bits on tape containing special non-data control and check bits and bounded on both sides by "inter-record gap" tape marks) in accordance with IBM/360 tape physical record specifications. This enables reading of the data tapes by the IBM/360 without intermediate tape format conversion procedures. Approximately 30 days of data is written on a tape, the tape deck-magnetometer digital data recording unit being unattended for this length of time.

The phrase "set of H,D,Z,R data" used throughout this documentation signifies the values of the H,D,Z, and R data readings sampled at the same instant of time and recorded on tape in the normal course of operation of the ground station digital magnetic data recording unit.

PROGRAM PURPOSE AND OUTPUTS

The purpose of the program is to convert the raw H, D, Z coordinate system geomagnetic field component data count readings and auxiliary experiment channel R readings (if channel R is being used for magnetic data) on tapes from ATS-5 ground stations into gamma (equal to 10^{-5} gauss) units for a selected time interval of interest, and to display the results.

The display output of the program is as follows:

1. time-ordered numerical print-out of H,D, Z (in gamma units), and the name of the experiment on the R channel and the R data values (see sample in Appendix E).

- 2. graphical plot of the instantaneous H,D, and Z values plotted individually as a function of time on Stromberg Carlson 4020 plotter microfilm (called Plot B, see sample in Appendix F).
- 3. graphical plot of 30-second average H, D, and Z values (in gammas) plotted individually as a function of time on SC 4020 plotter microfilm (called Plot C, see sample in Appendix G).

NOTE: The time assigned to each averaged H, D, or Z value is the mid-time of the 30-second time interval containing the data used for calculating the respective average.

GROUND STATION DATA TAPE FORMAT

The designed tape format is as follows (see Appendix B for detailed schematic diagram of the tape format):

- 1. Physical record (alternatively called "block") control bits and interrecord gap length within IBM specifications.
- 2. Physical record length 7200 IBM/360 bytes.
- 3. Logical record characteristics (see Appendix B for detailed description of a logical record).
 - A. Length -72 IBM/360 bytes
 - B. Logical records per block 100
 - C. Data contents of a logical record (in order of occurrence on tape)
 - 1) time (day of year, hour, minute, second) of first of the ten sets of H, D, Z, R data counts in the logical record
 - 2) station ID code
 - 3) R experiment channel code
 - 4) data year code
 - 5) first of the ten sets of H, D, Z, R data counts in the logical record

- 6) 48 dummy bits not presently used
- 7) the nine remaining sets of H, D, Z, R data counts of the logical record
- D. Time span covered by logical record depends on the time interval between sampling of each set of H, D, Z, R data. This time interval is set manually by a control on the Magnetometer Field Monitor (see "Design Sample Time Intervals" below). The data sample time interval is usually one second.
- E. Data files per tape -1

SPECIAL SITUATIONS ON DATA TAPE

The actual tapes differed from the original design specifications in some blocks as follows:

- 1. block length less than 7200 bytes (some as short as one byte)
- 2. control bits not within IBM specifications
- 3. data sampling time interval different from design value
- 4. year code (see "ID Codes" below) for 1969 wrong (for entirety of tape)
- 5. day of year of a logical record occasionally wrong
- 6. occasional blocks with incorrect format in that the block does not begin with the beginning of a logical record (the data time field) causing all following logical records of the block to also be off-format
- 7. spurious extra ends of file on data tape

The IBM/360 reacts to short blocks (less than 18 bytes) and/or incorrect control bits as though an I/O error for the block involved occurs. This causes multiple re-reads of the block by the IBM/360 rapidly wearing through the data tape.

STEPS TAKEN TO ACCOMMODATE SPECIAL SITUATIONS ON GROUND STATION DATA TAPES

- 1. A computer that re-reads blocks with faulty control bits and/or length less than 18 bytes zero times was found. A program for it, shown in Appendix I, was written to copy blocks of the original tape padded out to 7200 bytes by hex 9's if short and with a hex 1 inserted in the last hex digit of the dummy bit field of the first logical record as an indicator if read with I/O error. All data of a block with such an indicator is flagged with an "F" in the microfilm display and numerical print-out since data read with an I/O error may be unreliable. The copied data tape has no faulty control bit or short block problem when run on the IBM/360. This computer used for copying is the IBM/1800 located in Goddard Space Flight Center, Building 2 ground floor. It can be operated by the programmer himself.
- 2. The program calculates the data sampling time interval for the data of a logical record (with valid time information) by dividing by 10 the difference between the first data sample time (the first 9 hex digits of the logical record) and that of the next consecutive logical record if it has valid time information. This handles any operationally imposed data sampling time interval changes within the block. Tests determining what constitutes valid times are described in (3.) following. The 10 sets of H, D, Z, R data of any logical record having a data sampling time interval differing from design specifications are processed as usual, but are flagged with a "T" in the microfilm display and the numerical print-out.
- 3. A logical record which has an invalid time field (first 9 hex digits) or which is followed by a logical record having an invalid time field (making determination of data sampling time interval impossible) is not processed. Following are conditions defining an invalid time field of a logical record:
 - A. day of year, hour, minute, or second having an impossible value, e.g., day of year greater than 366 or less than 1 (if this occurs the time field of the logical record is set to zero as an indicator instead of the equivalent number of milliseconds since the "ZERO YEAR" time origin as described below).
 - B. time of the logical record greater than time of following logical record (chronological order test).

- C. time difference between logical record and the following one greater than maximum value (10 seconds) prescribed by design specifications (guards against the use of an incorrect data sampling time interval in assigning a time to each of the 10 sets of H, D, Z, R data in the logical record).
- 4. To enable processing of the data in the occasional short blocks (less than 7200 bytes) on the original tape the program puts hex 9's in that part of the fortran array (IDAT) receiving the data block which is not filled by the block due to its shortness. In this way data from a previous block will not remain at the end of the array to be incorrectly interpreted as data of a new block. Thus, the program will ignore any blocks having hex 9's in the time field of the 2nd logical record or before. Also, any logical records having hex 9's in it or in the time field of the following logical record is recognized as the last logical record of a short data block and is not processed.
- 5. In the absence of the correct year code field in all logical records of data tapes of year 1969, (year code for '69 as well as '70 was zero), the change of day of year to a value less than 365 was used to indicate beginning of 1970 data. Due to the unreliability of the year code field in the data tapes, the correct year at the beginning of the tape being processed is supplied by means of a fortran statement placed in the main program.
- 6. Data tapes with spurious ends-of-file are processed by means of a specially modified program deck which considers the tape as one having multiple IBM/360 data sets and uses the required special IBM 360 job control cards. The actual number of files on the tape must be entered into this special program which is not shown in this publication. A copy of this program can be obtained from the author.
- 7. Avoidance of data loss in tape blocks with format errors was accomplished by use of special program logic. This logic searches for the first occurrence in the tape block of a distinctive bit configuration (the dummy bit field of the logical record as shown in Appendix B). Since this relatively easy to locate bit configuration occurs at a fixed position within a logical record, the hexadecimal digit beginning the first logical record in the tape block is also determined once the first dummy bit configuration is found. If the hexadecimal digit beginning the first logical record is not the first hexadecimal digit in the tape block, the fortran array containing the data of the tape block is shifted so that it is before processing continues. This format error corrector fails if

the logical record length is not constant as occasionally happens. The program utilizing this corrector logic is not shown in this publication. Copies of this program can be supplied however.

STATION, ADDITIONAL EXPERIMENT CHANNEL (R), AND DATA YEAR ID CODES

See Appendix B for where these codes appear in each logical record of the data tape. The field length for each code is 4 bits, i.e., one hexadecimal digit. The codes, in hexadecimal, follow:

1. Station Codes

- A. 1 = LYNN LAKE
- B. 2 = THOMPSON
- C. 3 = WINNIPEG
- D. 4 = THE PAS

2. Additional Experiment Channel (R) Codes

- A. 0 = not used
- B. 1 = H magnetic field component
- C. 2 = D magnetic field component
- D. 3 = Z magnetic field component
- E. 4 = proton experiment (total magnetic field)
- F. 5 = other experiment (photometer, etc.)

3. Year Codes

- A. 9 = 1969
- B. 0 = 1970
- C. 1 = 1971

D. 2 = 1972

E. 3 = 1973

etc.

DATA TIME VALUE ASSIGNMENT

Each logical record has 10 sets of H, D, Z, R data each set corresponding to an instant of time. Only the time (in day of year, hour, minute, second) of the first set of H, D, Z, R data is given in the logical record. The time for each of the 9 remaining sets of H, D, Z, R data is obtained by adding to the time of the first H, D, Z, R set the data sampling time interval (between each H, D, Z, R set of data) the number of times appropriate for the particular set of H, D, Z, R to which a time value is being assigned. For example, to get the time of the third H, D, Z, R set the data sampling time interval is added to the time of the first H, D, Z, R set twice. As mentioned above, the data sampling time interval for the logical record is the difference between the time of its first set of H, D, Z, R data and the time of the first H, D, Z, R set in the next consecutive logical record divided by 10. If either of these two times do not pass the time validity tests described above, no data sampling time interval is calculable and the data of the logical record is ignored. This method enables automatic handling of change of the operating sampling time interval wherever it occurs on the data tape.

To do computations with time, such as time addition to get data point times, or taking time difference between begin time of a microfilm frame and the data point time being plotted (to get its abscissa in one system of units as required by plot subroutines), etc., any time value used in the program is converted from calendar units (year, day of year, hour, minute, second) to the equivalent number of milliseconds the time value is from an arbitrary time origin. This time origin (called ZERO YEAR) is prior to the earliest time value in the data tapes so that the "number of milliseconds since ZERO YEAR" equivalent of a data point time will never be negative. The arbitrary point in time taken as ZERO YEAR is zero hour, minute and second of the first day of any year if this time precedes the earliest data to be processed. However, ZERO YEAR must not pre-date the data so much that the "number of milliseconds since ZERO YEAR" expressing the latest time used in the program is so large as to exceed the computer storage allotted to it. In this program, times (in "milliseconds since zero year") are in fortran double precision which allows (for the IBM/360) processing of times near enough to ZERO YEAR so that their equivalent in "milliseconds since ZERO YEAR" is 17 significant digits or less. Thus many years of data

can be processed without change of the ZERO YEAR (set by a fortran arithmetic statement to 1969 at beginning of main program).

The program uses two auxiliary subroutines for operations on time. These are subroutine MSZRDP to go from time in calendar units (year, day, hour, minute, second) to the equivalent in milliseconds since ZERO YEAR, and subroutine MSCLDP to go from "milliseconds since ZERO YEAR" to the more convenient equivalent in calendar units (year, day of year, hour, minute, second).

MAGNETIC FIELD MONITOR DESIGN DATA SAMPLE TIME INTERVALS

The operating data sample time interval is set by a control switch on the Magnetic Field Monitor and is seldom changed. The usual data sample time interval is one second, i.e., the time interval between times of consecutive sets of H, D, Z, R data is usually one second. The possible data sample time intervals by original monitor design are .1 sec, 1 sec, 2 sec, 5 sec, or 10 sec.

PLOT B (NON-AVERAGED DATA DISPLAY) FORMAT

Each microfilm frame consists of a graph of the H component (in gammas) as a function of time, a similar D component graph, and a similar Z component graph of the same frame. See Appendix F for a sample plot B.

The time scale for the H, D, and Z component plots on the frame is the same and depends on the data sampling time interval for the first set of H, D, Z data of the microfilm frame so that the time scale optimum for the prevailing sampling time interval at the start of the plots is used. The time scale (the data time length covered in the microfilm frame) that we considered optimum as a function of data sampling time interval is as follows:

DATA SAMPLING	DATA TIME LENGTH
TIME INTERVAL	COVERED IN FRAME
.1 second	1 minute
1 second	6 minute
2 second	12 minute
5 second	1 hour
10 second	1 hour

The program causes the begin time and end time of any plot B to delimit an integral multiple of the chosen data time length from time zero of the day of data, and to include at least one data point positioned properly on the time scale even though data gaps may exist. This facilitates data comparisons for different days. A vertical line appears on the microfilm frame every sixth of the selected data time length covered by the frame. The time intervals between these vertical lines are further sub-divided by 10 short vertical "tic" marks.

The vertical scale for the H (in gamma units) plot of the frame depends on the maximum and minimum values of the H component values being displayed in the plot. Similarly for the vertical scale of the D plot, also the vertical scale of the Z plot. Only six vertical scales, i.e., low and high limit of vertical scale for a given component are possible. The specific vertical scale chosen for the component plot on the particular microfilm frame is the first of the following six scales which includes both the maximum and the minimum of the component values displayed in the plot.

VERTICAL PLOT SCALES

(the one displaying the component with the best resolution is chosen for the microfilm frame)

> -60. to +60. -150. to +150. -300. to +300. -600. to +600. -1200. to +1200. -2400. to +2400.

A horizontal line appears on the respective component plot on the microfilm frame every sixth of the data range (in gamma units) covered by the selected vertical scale. The scale between these horizontal lines is further sub-divided by 10 short horizontal "tic" marks.

PLOT C (AVERAGED DATA DISPLAY) FORMAT

A Plot C appears every time data spanning an hour of time has been displayed by plot B's. Its purpose is to summarize (as 30-second time interval averages) for each individual component the instantaneous data displayed in the intervening (an 'hour's worth') plot B's. This provides a 'quick-look' capability to the

scientist using the microfilm. For example, a plot C summarizes and appears after every ten plot B's when the plot B data time length is six minutes (which is the norm).

The scheme for the vertical and horizontal scales for plot C are the same as those for plot B described above except the horizontal scale (the time scale) is non-variable and always covers one hour of data. See Appendix G for a sample of plot C.

EQUATIONS USED IN PROGRAM

1. To obtain the H, D, or Z field components values from magnetometer "counts" for the individual component as recorded on the data tape.

FIELD COMPONENT (in gammas) = COUNTS FOR COMPONENT × .976408 - 2000.

2. To provide reliability that a 30-second average component value does approximate the true field component value at the time assigned it, no average component value is established for the 30-second interval unless at least 1/3 of the maximum number (30 seconds divided by the data sampling time interval) is available in the 30-second interval for computing its average. Thus, the minimum number of component values required (CPCTMN) for getting a 30-second average component value is given by

CPCTMN =
$$\frac{1}{3} \cdot \frac{30000}{\text{TSPLST}} = \frac{10000}{\text{TSPLST}}$$

where TSPLST is the data sampling time interval at end of the 30-second interval. TSPLST rarely changes.

SPECIFICS OF PROGRAM LOGIC

Only the general features of the program are discussed here since in-depth details intended to expedite the programmer's learning task appear as numbered comments in the main program listing in Appendix C. Numbering of the comments makes it possible to locate the specific group of Fortran statements being explained in the text below which cites comment numbers, or being represented by flow chart blocks (Appendix A has general flow chart, Appendix D has detailed "Autoflow" flow chart) adjacent to which the corresponding listing comment statement numbers appear.

1. Main Program

The scheme of data processing used in the main program resulted from attempting to attain a specific goal: to write the most brief, straightforward, efficient program for processing the given data. The ability to process only selected time intervals (by designating their begin and end times, i.e., TI, TF's on data cards read by the program) or the entire data tape was also included in the program. The general data processing scheme used here for ATS-5 ground station data has also been used quite successfully with large volumes of data from other sources (ATS-5 PCM and PFM flight data, and also OGO-6 flight data).

The data processing steps done by the main program are:

- A. read next TI, TF or end-of-computer run indicator (XX) on data card (comment 2); the XX card is always last data card.
- B. read next block on data tape until last time of block is greater or equal to TI (comments 2 to 10); terminate run if end-of-tape encountered in this "search mode".
- C. get begin time of block accessed by previous step; back to step "A" if this begin time is greater than TF, i.e., beyond present TI, TF (comment 10).
- D. process the logical records of the block that are within the present TI, TF by storing the time and the H, D, Z (in gammas) and R of each of the 10 sets of H, D, Z, R counts of each logical record in the arrays ("B arrays") containing the data to be displayed by a plot B (comments 11 to 34).
- NOTE: The extra step of storing data in an array instead of plotting it directly is necessary in order to pre-determine the best vertical scale for the H, D, and Z plots individually before doing the plot B or the plot C.

During this processing, 3 situations may occur:

- 1) data time larger than TF encountered in this event go to step "A" (comment 16).
- 2) end of block on data tape reached in processing in this event to to step "B" (comment 15).
- 3) data time larger than end time of present plot B encountered in this event go to step "E", etc., below (comment 22).

- E. get 30 second average data points for plot C from the B array before it is filled by data for the next plot B; store these averaged data points in an array termed the "C array" (comments 22 to 31).
- F. if, in step "E", a 30 second average data point with time greater than end time of present plot C is encountered, use the data in present C array to do a plot C. After this plot C is done, the C array is again available for storing more 30 second averaged data for the next plot C starting with its first location (comments 26 to 28).
- G. now that the data in the B array has been utilized (for averaging), use this data to do the plot B whose end time was just exceeded; after this, the B array is again available. Continue storing the data from the logical records into the B array starting with their first location (comments 31 to 34).
- H. computer run ends by reading the last TI, TF data card which is always the symbol XX indicating the computer run is to be terminated (see step "A"), or by encountering end-of-tape (comments 2 and 7).

2. Subroutine MSZRDP (IYR, IDY, IHR, MN, ISEC, TM)

- A. Purpose to get "millisecond since ZERO YEAR" equivalent in double precision of a time known in calendar units, i.e., year, day of year, hour, minute, and second.
- B. Calling Sequence -
 - 1) IYR = last 2 digits of year (fortran integer)
 - 2) IDY = day of year, i.e., Julian day (fortran integer)
 - 3) IHR = hour of day (0 to 24, fortran integer)
 - 4) MN = minute (fortran integer)
 - 5) ISEC = second (fortran integer)
 - 6) TM = the equivalent in 'milliseconds since ZERO YEAR' (fortran double precision variable) of the time specified by the 5 preceding calling sequence elements.

C. Common Section — one only, named ZROYR, to communicate value of ZERO YEAR, in common with main program in which value is set (for explanation of the term ZERO YEAR see the section above entitled "Data Time Value Assignment").

3. Subroutine MSCLDP (TM, IYR, IDY, IHR, MN, SEC)

A. Purpose — to get the calendar units equivalent, i.e., year, day of year, hour, minute, second of a time known in "milliseconds since ZERO YEAR". Also returns month and day of month (see "common sections" below).

B. Calling Sequence -

- 1) TM = the equivalent in "milliseconds since ZERO YEAR" (fortran double precision variable) of time specified by the 5 following calling sequence elements outputted by this subroutine.
- 2) IYR = last 2 digits of year (fortran integer).
- 3) IDY = day of year, i.e., Julian day (fortran integer).
- 4) IHR = hour of day (0 to 24, fortran integer).
- 5) MN = minute (fortran integer).
- 6) SEC = second (fortran single precision floating point variable).

C. Common Sections -

- 1) name is ZROYR, used to communicate value of ZERO YEAR to this subroutine, in common with main program in which value is set.
- 2) name is DATE, used to return month (MNTH, typed as fortran integer but contains BCD alphabetic information) and day of month (IDYMTH, fortran integer) to calling program.

4. Subroutine ATSGRT (IWD1, IWD2, IYR, TM)

A. Purpose — to get the data time presented in the logical record in "milliseconds since ZERO YEAR".

B. Calling Sequence -

- 1) IWD1 = a fortran integer word consisting of the first 4 bytes of the logical record, i.e., day, hour, minute and 10's digit of second (see format of the logical record in Appendix B).
- 2) IWD2 = a fortran integer word consisting of the second 4 bytes of the logical record needed only to get 1's digit of seconds.
- 3) IYR = last 2 digits of year of data, set by arithmetic statement at beginning of the calling program (the main program) instead of picked-up from data tape since the data year code for year 1969 is incorrect on the tapes.
- 4) TM = the equivalent in "milliseconds since ZERO YEAR" (fortran double precision variable) of the data time presented in the logical record.

5. Subroutine PICK (ITO, IFROM, ISW, IOFST, NRBTS)

- A. Language IBM 360 assembly language.
- B. Purpose to unpack a bit string of the logical record constituting one of its data fields and move it to a fortran integer word in the calling program which then uses it.
- C. Calling Sequence (all elements are integers) -
 - 1) ITO = address of fortran word where bits are to be moved and right-adjusted in this word.
 - 2) IFROM = address of fortran word containing the bit string comprising the data field wanted.
 - 3) ISW = word combination switch, when non-zero allows more than one fortran word to be used in building the bit string being returned as a data field to the calling program in the fortran word specified by ITO above.
 - 4) IOFST = number of bits that contents of word specified by IFROM above must be shifted left in order to left-adjust the bit string to be moved to the calling program.

- 5) NRBTS = number of bits comprising bit string, i.e., data field wanted.
- 6. Subroutine ATSGPB (TMBARY, BT, IDBAR, ICT, IVSC, SCLM1, SCLM2, TIPB, TFRLTH (IHSC), IFLG, ITFLG)
 - A. Purpose contains all logic of program for doing the plot B for the Stromberg Carlson 4020 microfilm plotter; plots all data presently contained in the B arrays which are communicated to it; the data in the B arrays is within the specific begin and end time chosen by the main program and suitable to the present data sampling time interval (see section entitled "Plot B Format" above).
 - B. Calling Sequence (all input quantities to subroutine) -
 - 1) TMBARY = array containing time in double precision "milliseconds since ZERO YEAR" of each set of H, D, Z components plotted; dimensioned large enough (to 730) for the case in which the B array contains the greatest number of points to be plotted, i.e., when the data sampling time interval is 5 seconds with a 1 hour time length displayed on plot B.
 - 2) BT = two-dimensional array containing the individual H, D, Z component values to be plotted; first subscript selects component to plot (1 for H, 2 for D, 3 for Z); second subscript selects the H, D, Z set being plotted (data sampled at the same instant of time comprise a set). Each H, D, and Z value is in gamma units and fortran single precision.
 - 3) IDBAR = two dimensional fortran integer array containing the individual identification codes used primarily in SUBROUTINE ATSGPR; its first element is used in this subroutine to identify for labelling purposes the ground station whose data is being plotted; the first subscript selects which code (1 for station, 2 for identification of extra experimental channel R, 3 for indication of year of data); second subscript selects the H, D, Z set to which the codes apply.
 - 4) ICT = actual number of H, D, Z sets ("data points") in array BT (see above) to plot.
 - 5) IVSC = array containing as one of its 3 elements the subscript of the vertical scale (see below) that displays the H component with best resolution on this plot B; similarly for D and Z.

- 6) SCLM1 = array containing the plot B lower limit for each of the six possible vertical scales for the individual H, D, or Z component; the specific lower limit for the individual H, D, or Z plot on this plot B is selected by the SCLM1 array subscript value stored in the IVSC array element corresponding to the component (H, D, or Z). For example, the lower limit of the H plot vertical scale is the SCLM1 array element with subscript equal to IVSC(1). Similarly for D and Z.
- 7) SCLM2 = array defined similarly to array SCLM1 except SCLM2 contains the plot B upper limits for each of the six possible vertical scales.
- 8) TIPB = begin time in fortran double precision "milliseconds since ZERO YEAR" of this plot B; not necessarily a data time but it is the begin time of the closest integral multiple from zero instant of the data day of the time length selected for (see section entitled "Plot B Format") and displayed in this plot B that contains the first data time on the plot B.
- 9) TFRLTH (IHSC) = the element of array TFRLTH selected by the value of subscript IHSC; array TFRLTH contains the millisecond equivalent of the various data time lengths that plot B displays as selected by the prevailing (at beginning of data in the corresponding B array) data sampling time interval.
- 10) IFLG = array containing symbol for each set of H, D, Z values ("data point") indicating if the data tape block it is in was read by the IBM/1800 copy program and/or the actual data processing IBM/360 program with an I/O error. The symbol "F" is used to signify I/O error. Caution in interpreting such data should be used by the scientist. The blank symbol is used to indicate data read without an I/O error.
- 11) ITFLG = array containing symbol for each set of H, D, Z values ("data point") indicating if the data sampling time interval value for the set is equal to one of the design values (stored in array TINT). The symbol "T" is used to mark a data point at which the data sampling time interval is unexpected. Data marked by a "T" is not necessarily wrong. The blank symbol is used to indicate data at which the data sampling time interval is equal to a design value.

C. Common Section — name is DATE, used to return month (MNTH, typed as fortran integer, but contains BCD alphabetic information) and day of month (IDYMTH, fortran integer) to calling program.

7. Subroutine ATSGPR (TMBARY, BT, R, IDBAR, IFLG, ITFLG, ICT)

A. Purpose — this subroutine is called only if the symbol "PRT" appears on the TI, TF data card (see below); contains all logic of the program to do numerical print-out of the H, D, Z magnetic field component values in gamma units in chronological order for data within the currently selected TI, TF. Included in this print-out is the data of the additional experimental data channel (R) and the name of the experiment on channel R. If the R data is either the H, D, or Z component it is in gamma units, otherwise the R data is printed out exactly as found on the data tape, i.e., in counts. The data printed out by a call to this subroutine is the contents of the present plot B array at time of the call.

B. Calling Sequence -

- 1) R = array containing all R channel data values for data times in present plot B array; in gamma units if R channel has magnetic data, otherwise in counts; in either case, fortran single precision.
- 2) for explanation of other elements of calling sequence see explanations given for them under SUBROUTINE ATSGPB.

C. Common Section -

name is DATE; communicates month (integer-type fortran variable MNTH containing 3-character alphabetic name of month), and day of month (fortran integer IDYMTH) communicated from SUBROU-TINE MSCLDP (see above) to this subroutine for printing out time information.

8. Subroutine ATSGPC (TMAV, BTAV, ISBSTA, ICTC, IVSC, SCLM1, SCLM2, TIPC)

A. Purpose — contains all logic for doing an SC 4020 microfilm frame (a plot C) displaying the 30 second averaged H, D, and Z magnetic field component values in individual plots on the frame from data in the C arrays each time called.

B. Calling Sequence -

- 1) TMAV = array containing times in fortran double precision "milliseconds since ZERO YEAR" of the H, D, Z 30 second average component values displayed in this plot C; dimensioned large enough (to 130) to hold maximum number of data times (at 30 second spacing) contained within the fixed data time length displayed by a plot C (1 hour).
- 2) BTAV = two-dimensional array containing the H, D, and Z 30 second average component values to be individually displayed on plot C; first subscript selects component (1 for H, 2 for D, 3 for Z); second subscript selects the set of average H, D, Z values being individually plotted where "set" in this usage signifies an average H, D, and Z value all applying to the same assigned data time (stored in array TMAV above).
- 3) ISBSTA = ground station identifier code used to choose ground station name with which to label this plot C; the code used comes from the logical record that contains the first set of instantaneous H, D, Z component data values included in the B array last used for averaging and filling of the C arrays.
- 4) ICTC = actual number of 30 second average H, D, Z component value "sets" in C array to be displayed on this plot C.
- 5) IVSC, SCLM1, SCLM2 = see explanations for these arrays given under calling sequence for SUBROUTINE ATSGPB.
- TIPC = begin time in fortran double precision "milliseconds since ZERO YEAR" of this plot C; not necessarily a data time but it is the begin time of the closest integral multiple from zero instant of the data day of the fixed plot C time length (1 hour) which contains the time of the first 30 second average H, D, Z component values on the plot C.

C. Common Section -

1) name is DATE; explanation similar to that for common section DATE in subroutine ATSGPB above.

9. Subroutine ERRSET (IERNO, INOAL, INOMES, ITRACE, ADDUSE, IRANGE)

A. Purpose — this is an IBM/360 Fortran Programming System subroutine. It prevents the operating system from terminating the computer run if multiple short blocks, i.e., of length (in bytes) less than that specified by the Job Control Language (see Appendix J) for the data set, are encountered on the ground station data tape. This "short block" situation does sometimes occur due to tape deck operation deviation from design.

B. Calling Sequence -

1) see explanation of this subroutine in IBM/360 System Reference Manual "Fortran IV (G and H) Programmer's Guide" (form number C28-6817-0) in Chapter entitled "Extended Error Message Facility".

10. Subroutine PLTND

A. Purpose — this is one of the subroutines of the programs used in generating the SC4020 plotter tape for microfilm production. It must be the last SC4020 subroutine call in the program in order to force emptying of any residual contents in the SC4020 output tape buffers at the end of the computer run. It is part of the SCORS subroutine package for the SC4020 plotter described in the publication "SC4020 Microfilm Recorder User's Manual" by Computer Sciences Corp.

11. Subroutine EXIT

- A. Purpose this is an IBM/360 Fortran Programming System subroutine. It is used to terminate program execution by returning control to the IBM/360 Operating System. See IBM/360 System Reference Manual "Fortran IV Language" (form number C28-6515-7) in Appendix C: Fortran-Supplied Subprograms.
- NOTE: All subroutines of the program which are not described above are used in generating the SC4020 plotter tape for microfilm production. They are part of the SCORS subroutine package for the SC4020 plotter described in the publication "SC 4020 Microfilm Recorder User's Manual" by Computer Sciences Corp.

12. Program Input/Output Details

For a more in-depth explanation of input/output details than that following see Appendix J which contains a listing of the actual IBM/360 Job Control Language

used in the program. It also shows where the TI, TF selector cards go in the deck and their format.

A. Inputs

- 1) the data tape from the ATS-5 ground station
 - a) read by fortran in the main program on unit 11
 - b) tracks 9
 - c) mode binary (as usual for 9 track tapes)
 - d) density 800 BPI (as usual for 9 track tapes)
 - e) format see Appendix B and section entitled "Ground Station Data Tape Format" above.

NOTE: The RECFM (physical record format) parameter on the DD card for the input data tape was set to U (meaning undefined) because the original data tapes may have occasional short length physical records.

- 2) the TI, TF selector program input cards
 - a) read by fortran in the main program on unit 5
 - b) position in deck immediately after the GO.DATA5 DD * JCL card of the program deck in chronological order (see Appendix J)
 - c) format data fields other than "PRTSEL" are read by the I fortran field specification and must therefore be right-adjusted in the card columns assigned to the data field.

data field main program fortran variable and description

card columns assigned to the data field on the input card

SYM, causes termination of computer run if the characters XX are punched in the card columns assigned to it 2, 3

IYRI, last 2 digits of the year of the begin

time (TI) of the data interval selected for processing by this input card, for example if the year is 1970, the char- acters 70 are punched	7, 8
IDYI, the day of year of the begin time (TI) of the selected data interval	10, 11, 12
IHRI, the hour of the begin time (TI) of the selected data interval	14, 15
MNI, the minute of the begin time (TI) of the selected data interval	17, 18
ISECI, the second of the begin time (TI) of the selected data interval	20, 21
IYRF, the year of the end time (TF) of the selected data interval	34, 35
IDYF, the day of year of the end time (TF) of the selected data interval	37, 38, 39
IHRF, the hour of the end time (TF) of the selected data interval	41, 42
MNF, the minute of the end time (TF) of the selected data interval	44, 45
ISECF, the second of the end time (TF) of the selected data interval	47, 48
PRTSEL, the variable on the input card used to select the time-ordered numerical data value paper print-out display (see Appendix E for sample) of the data in the time interval selected by this TI, TF card. This display is outputted only if the characters PRT are punched in the columns assigned. If the assigned columns are left blank this display is not outputted. Variable PRTSEL is typed integer and read in by means of fortran field specification A.	50, 51, 52

NOTE: As stated above, when more than one TI, TF input card is used they should be put in chronological order as indicated in Appendix J. If they are not, the data selected by the TI, TF cards which are out of chronological order with respect to the first TI, TF input card will not processed. However, the data selected by the first TI, TF card will be processed in any case if it is contained on the data tape mounted.

NOTE: As explained in the section above entitled "Data Time Value Assignment" the TI, TF input cards must only specify data time intervals later in time than the ZERO YEAR value set in the program.

NOTE: As mentioned above, to terminate the computer run properly, a card with the characters XX punched in columns 2 and 3 must follow the last TI, TF card.

B. Outputs

- 1) the tape which the Stromberg Carlson Plotter uses as its input to produce the microfilm consisting of the plot B display (see Appendix F for sample) with the plot C display (see Appendix G for sample).
 - a) written by fortran in one or more of the subroutines of the new SCORS Stromberg Carlson 4020 plotter package on unit 10.
 - b) tracks 7
 - c) mode binary
 - d) density 556 BPI

NOTE: In general several SC4020 plotter tape reels are outputted in a computer run since so many microfilm frames are necessary to display the data on a full ATS-5 ground station data tape. For such a full tape, i.e., one containing 30 days of data, approximately 7400 microfilm frames are produced from ten full SC4020 plotter tape reels outputted by the computer run. The new SCORS SC4020 plotter subroutine package and the IBM/360 Job Control Language DD card for fortran unit 10 shown in Appendix J in conjunction have all necessary logic for the program to request a blank tape to continue outputting SC4020 microfilm plotter tapes when a previous tape is filled up.

- 2) the optionally selected (see discussion of selector variable PRTSEL in the explanation of the TI, TF input card above in this section) time-ordered numerical data value paper printout display.
 - a) written by fortran in subroutine ATSGPR on unit 6
 - b) see sample of this display in Appendix E
- 3) printed messages giving the beginning and end time (TI, TF) of each data time interval appearing on an input card read by the program; the beginning and end time of the mounted ATS-5 ground station data tape (the end time is printed only if the end-of-tape is encountered during processing of the data); the number of SC4020 plotter microfilm frames residing on the plotter input tapes produced by the computer run.
 - a) written by fortran in the main program on unit 6.

ACKNOWLEDGEMENTS

The author wishes to express his gratitude to the following people for completing the team that made possible this computer exposition of exciting new additions to geophysical knowledge by advanced instrumented monitoring methods: T. L. Skillman, the principal investigator for the ATS-5 Magnetic Field Monitor, for designation of data displays; Dr. Paul Serson and L. Law of the Canadian Dominion Observatory for installation and maintenance of the magnetometers at the ATS-5 ground stations; S. Billingsley for design and installation of the digital recording units; O. Clark for data tape format design and the writing of subroutine PICK used in the program; Dave Fisher of IBM at Goddard Space Flight Center for writing the IBM/1800 computer program for copying and correcting the original data tapes.

APPENDIX F

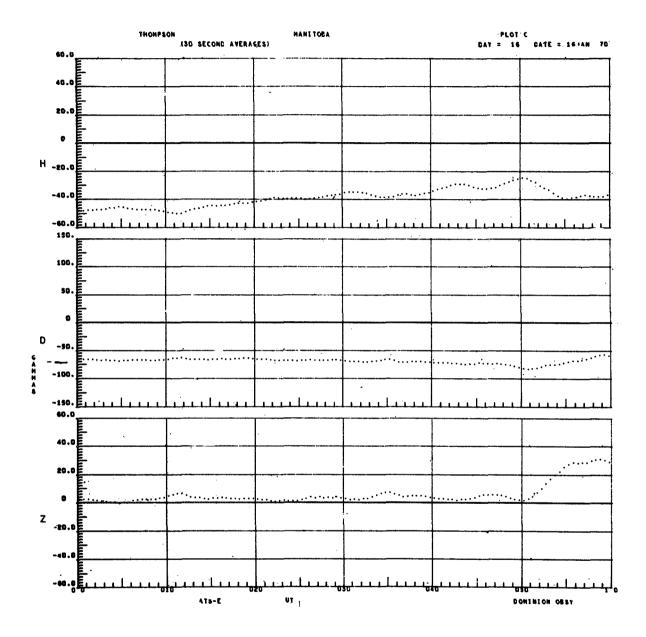

SAMPLE OF THE MICROFILM NON-AVERAGED

DATA DISPLAY OUTPUT (PLOT B)

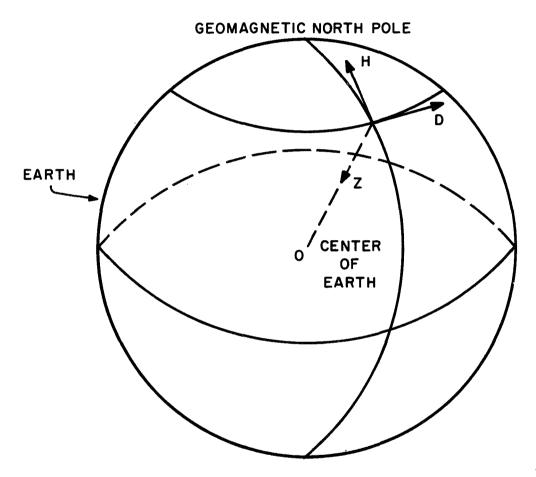

APPENDIX G

SAMPLE OF THE MICROFILM AVERAGED DATA DISPLAY OUTPUT (PLOT C)

APPENDIX H

DEFINITION OF THE H, D, Z DATA COORDINATE SYSTEM

H,D,Z Coordinates. On any spherical surface concentric with the earth the H axis points to the geomagnetic north, the D axis to the geomagnetic east, and the Z axis to the center of the earth.

APPENDIX I

IBM 1800 PROGRAM FOR COPYING
ATS-5 GROUND STATION TAPES

Written by Dave Fisher of IBM at Goddard Space Flight Center
